

Can it be used without a network optical module

Overview

A passive optical network (PON) is a point-to-multipoint fiber network architecture that uses optical splitters to deliver high-bandwidth services from a single fiber to multiple end users without requiring active electronics in the field. These modules typically consist of a transmitter, which converts electrical signals into a light signal, and a receiver, which converts the received signal back. Passive optical networking (PON), like active optical networking, uses fiber-optic cabling to provide Ethernet connectivity from a main data source to endpoints. While there are many subtle differences, a clear distinction between active optical networking and PON topology is PON's use of a 20L needs to be plugged in with an SFP module to work normally. It is recommended to use a TP-Link SFP module on M. Two MC220Ls with the same SFP module can work cooperative RX port of the other using valid link for FX Port.

What Is Passive Optical Networking (PON)?

Passive optical networking (PON), like active optical networking, uses fiber-optic cabling to provide Ethernet connectivity from a main data source to endpoints.

Scenario 1: Connect Devices with and without Optical Interfaces

An MC220L can also cooperate with an MC200CM or an MC210CS. However, the mode and wavelength of the SFP module used in MC220L must be the same as the opposite end.

What is PON? Passive Optical Networks Explained

A passive optical network (PON) is a fiber-based access network that uses unpowered optical components to deliver high-speed connectivity from a service provider to many end users.
